

COMPUTER LOGIC AND DIGITAL CIRCUIT DESIGN (PHYS306/COSC330): UNIT 0

Jordan Hanson

February 6, 2020

Whittier College Department of Physics and Astronomy

SUMMARY

Reading: Digital Fundamentals ch. 2-1 through 2-7

1. Number representation
2. Binary conversions
3. Binary arithmetic
4. *The floating-point system*
5. Hexadecimals, Binary-Coded Decimals (BCD), Gray codes, and ASCII

NUMBER REPRESENTATION

Questions:

- A simple question: how many students do we have in this class?
- Una simple pregunta: ¿Cuántos estudiantes tenemos en esta clase?
- Une question simple: Combien d'étudiants est-ce que nous avons dans cette classe?

What languages do computers speak? How can we store and transmit numbers through circuits? (We cannot use voltage magnitudes).

Consider the number 37

Numbers

- 0d37
- 0b100101
- 0x25

Expanded notation

- $3 \times 10^1 + 7 \times 10^0$
- $1 \times 2^5 + 1 \times 2^2 + 1 \times 2^0$
- $2 \times 16^1 + 5 \times 16^0$

Consider the number 412

Numbers

- 0d412
- 0b110011100
- 0x100

Expanded notation

- $4 \times 10^2 + 1 \times 10^1 + 2 \times 10^0$
- $1 \times 2^8 + 1 \times 2^7 + 1 \times 2^4 + 1 \times 2^3 + 1 \times 2^2$
- 1×16^2

Number representations - Digits, weights, and a common base

- A number is written with **digits** that have **weights**.
- A **weight** is a power of a **base**.
- At right, the **base** is ten, and the **weights** are 10^2 , 10^1 , and 10^0 .
- The **digits** are four, one, and two.
- The digits cannot represent numbers larger than the base.

Expanded notation

- $412 =$
 $4 \times 10^2 + 1 \times 10^1 + 2 \times 10^0$

Number representations - (Aside) please use scientific notation, and here is why: digit minimization!

- Scientific notation **factors the largest weight**.
- Results in weights that are less than one.
- Weights that are less than one go to the right of the **decimal point**.
- Return here with *floating-point* representation.

Expanded notation

- $412,000,000 =$
 $4 \times 10^8 + 1 \times 10^7 + 2 \times 10^6 +$
 $0 \times 10^5 + 0 \times 10^4 + 0 \times 10^3 +$
 $0 \times 10^2 + 0 \times 10^1 + 0 \times 10^0$
- $412,000,000 =$
 $4.12 \times 10^8 = (4 \times 10^0 + 1 \times$
 $10^{-1} + 2 \times 10^{-2}) \times 10^8$

Number representations - (Aside) please use scientific notation, and here is why: arithmetic operations with large numbers!

1. $4200 \times 4200 = (4.2 \times 10^3)^2 = (4.2)^2 \times 10^6 \approx 16 \times 10^6$

2. $\approx 17.6 \times 10^6$ if you account for the 0.2 ...

1. $4000/3000 = 4 \times 10^3 \times \frac{1}{3} \times 10^{-3} = \frac{4}{3}$

2. $\frac{4}{3} \approx 1.33$

Expand the following numbers to expanded decimal notation:

- -10.432
- 800,000,144

Expand the following numbers to expanded binary notation:

- 10011010
- 11110000

Convert the following decimal numbers to binary notation:

- 260
- 560

BINARY CONVERSION

How did you do the conversions to binary? Is there a systematic way to do this?

- *Successive Approximation* - like a number puzzle (*Sum of Weights Method*)
 - *Successive Division Method* - Example of an algorithm
-

Successive approximation technique (does this remind you of doing division in your head?) $260 \dots 2^8 = 256$. Now we need four more... $4 = 2^2$. So $2^8 + 2^2 = 0b10000100$

What is 328 divided by 3? Ok try 100 because three times one hundred is close...

Successive Division Method

$$0d412 = 0b110011100 = 2^8 + 2^7 + 2^4 + 2^3 + 2^2$$

Algorithm:

1. Divide the decimal number by 2, and write down the remainder. This is the *least-significant bit* or LSB.
2. Keep dividing and recording the remainders in order, until you reach a dividend of 1.
3. $1/2 = 0r1$, so the *most-significant bit*, or MSB, is always 1.

Convert 412 to binary using the successive division method.

Convert the numbers at right to binary.

- $2^0 = 1$

- $2^1 = 2$

- $2^2 = 4$

- $2^3 = 8$

- $2^4 = 16$

- $2^5 = 32$

- $2^6 = 64$

- $2^7 = 128$

1. 93

2. 189

3. 270

Note: how many bits do you need for that last one? For binary, show that the highest representable number with n bits is $2^n - 1$.

Notice that we get a *repeating pattern* when we compare the conversion of 189 and 93. Why?

In decimal notation, we represent numbers $\in [0 - 1]$ with digits to the right of the *decimal point*.

In expanded notation:

$$42.42 = 4 \times 10^1 + 2 \times 10^0 \ . \ 4 \times 10^{-1} + 2 \times 10^{-2}$$

We have a similar notation in other number systems:

$$101.11 = 2^2 + 2^0 \ . \ 2^{-1} + 2^{-2}$$

Successive Multiplication Method

$$0d0.48 = 0b0.011110101 = 2^{-2} + 2^{-3} + 2^{-4} + 2^{-5} + 2^{-7} + 2^{-9}$$

Algorithm:

1. Multiply the decimal fraction by 2, and write down the *carry* (the 1 to the left of the decimal point, else 0). This is the *most-significant bit* or MSB.
2. Keep multiplying and recording the carries in order, to the desired precision.
3. Watch for repeating patterns.

Convert 0.48 to binary using the successive multiplication method until you identify a repeating pattern.

Convert the numbers at right to binary.

- $2^0 = 1$

1. 0.64

- $2^1 = 2$

2. 0.125

- $2^2 = 4$

- $2^3 = 8$

Which result should have a smaller number of digits, and why?

- $2^4 = 16$

- $2^5 = 32$

- $2^6 = 64$

- $2^7 = 128$

BINARY ARITHMETIC

Binary arithmetic, like decimal arithmetic, relies upon *carries* and *borrow*s. For example in decimal:

- $8 + 7 = 5c1 = 15$
- $3 + 4 = 7c0 = 7$
- $8 - 2 = 6b0 = 6$
- $10 - 5 = (0b10) - 5 = 5$
- $13 - 7 = (0b10) - 4 = 6$

In binary there are limited combinations, so we may form a set of addition and subtraction rules that describe all possibilities:

- $0 + 0 = 0$

- $1 + 0 = 1$

- $0 + 1 = 1$

- $1 + 1 = 0c1$

- $0 - 0 = 0$

- $1 - 0 = 1$

- $0 - 1 = 0b1$

- $1 - 1 = 0$

In the fourth rule for the addition set, the carry works the same way as a decimal carry: we add that 1 to the digit corresponding to the next power of 2. Similarly, in the third rule of the subtraction set, we subtract the 1 on the left side of the equation from a 1 from the digit corresponding to the next highest power of 2 available.

Complete the following additions and subtractions:

- $10 + 11$

- $10 - 11$

- $111 + 1$

- $111 - 1$

- $111 + 111$

- $111 - 111$

- $1010 + 101$

- $1010 - 101$

Binary multiplication stems from another set of rules:

-
- $0 \times 0 = 0$
 - $1 \times 0 = 0$
 - $0 \times 1 = 0$
 - $1 \times 1 = 1$

Multiply:

1. 10×10
2. 110×10

Binary division is exactly the same as decimal long division. Let's work these examples on the board:

- $145/12$
- $1101/101$
- $45/3$
- $111/10$

Of what logic operation does binary multiplication remind you?

We need a few tools to improve our arithmetic techniques in order to install these functions into circuits. Consider two actions:

- NOT to the bit sequence of a number: **1's compliment**
- Add 1 to the 1's compliment: **2's compliment**

Logical operator representation of these actions for 8-bits:

Figure 1: Representation of 1's complement.

Figure 2: Representation of 2's complement.

Exercises, and a realization for the purpose of 2's compliment.

Take the 1's
compliment of the
right-hand number,
and complete the
addition:

- $111 + (000)$
- $111 + (111)$

Take the 2's
compliment of the
right-hand number,
and complete the
addition:

- $111 + (000)$
- $111 + (111)$

Same, but drop the
MSB:

- $1010 + (1010)$
- $1100 + (1100)$

For what purpose are we going to use the 2's compliment?

The answer: representing negative numbers. For 2's *compliment form signed binary numbers*, the MSB is the **sign bit**. To convert to decimal, give the MSB a negative weight:

Example: 10101010

This is a negative number because the MSB is a 1. Converting in expanded form: $-2^7 + 2^5 + 2^3 + 2^1 = -128 + 32 + 8 + 2 = -86$.

Consider the effect on the maximum *range* of binary numbers after sacrificing the MSB to flag numbers less than zero. For 8-bits unsigned numbers, the range is [0-255]:

n -bits	8	16
Lowest unsigned	0	0
Highest unsigned	255	65535
Lowest signed	-128	-32768
Highest signed	127	32767

Table 1: The ranges of unsigned and signed numbers using n digits.

By changing the role of the MSB, we are not reducing the *range* of numbers, just its *location*. Related to *conservation of information*...

2's compliment, signed number representation and conversion, arithmetic with negative numbers

1. Write -278 in binary, 2's compliment form.
2. Convert -302 and 65 each to binary, and add them.
3. This number is in 2's compliment form: 11001101. Convert it to decimal.

HEXADECIMALS, BCD, GRAY-CODES, AND ASCII

Why do we use Hexadecimals?

<https://youtu.be/DqfnMzDhi38>

In case you get your butt stranded on Mars, and need to devise a rag-tag communication system from a camera-pole, is why.

HEXADECIMALS, BCD, GRAY-CODES, AND ASCII

Astronaut Watney needs a way to cram more information into shorter-length words...hexadecimals

Decimal	Binary	Hexadecimal
0	0000	0
1	0001	1
2	0010	2
3	0011	3
4	0100	4
5	0101	5
6	0110	6
7	1111	7
8	1000	8
9	1001	9
10	1010	A
11	1011	B
12	1100	C
13	1101	D
14	1110	E
15	1111	F

Table 2: Decimal, binary and Hexadecimal representations of numbers. What do you notice that is different between the representations?

Because $2^4 = 16$, we may group bits in bit sequences in groups of four, and read out the hexadecimal conversion:

$$0b11010010 = 1101\ 0010 = (13)\ (2) = 0xD2$$

On page 71 of DF: “It should be clear that it is much easier to deal with a hexadecimal number than with the equivalent binary number. Since conversion is so easy, the hexadecimal system is widely used for representing binary numbers in programming, printouts, and displays.”

It is probably important. What follows is a few examples of how I’ve encountered hexadecimal.

HEXADECIMALS, BCD, GRAY-CODES, AND ASCII

```
set key at 500,73 box on samplen 2 spacing 1.5 font "Courier,16" width 2
set xrange [1:1e3]
set yrange [0:180]
set format x "10^{%T}"
set rmargin 8
set lmargin 13
set tmargin 2
set bmargin 6
set xlabel "Frequency [MHz]" font "Courier,28" offset 0,-2,0
set ylabel "Phase (deg)" font "Courier,28" offset -5,0,0
set ytics scale 2 font "Courier,28"
set xtics scale 2 font "Courier,28" offset 0,-1,0
set style line 6 linecolor rgb "#000000" linewidth 5.000 dashtype 3 pointtype 2
set style line 7 linecolor rgb "#BBBBBB" linewidth 5.000 dashtype 3 pointtype 2
set linestyle 1 lc rgb "#000000" lw 5
set linestyle 2 lc rgb "#444444" lw 5
set linestyle 3 lc rgb "#888888" lw 5
set linestyle 4 lc rgb "#BBBBBB" lw 5
set linestyle 5 lc rgb "#DDDDDD" lw 5
set terminal postscript color enhance
```

Figure 3: A figure from a recent paper we published about neutrino signals in ice. The hexadecimals were used to encode the line-colors.

A math problem: If the RGB (red, green, blue) codes have the following format 0xA1B2C3, where each hex word (two characters) represents an amount of red, green, and blue (sequentially), how many distinct shades of each are technically possible? How many colors are therefore possible (even if a standard monitor could not resolve them)?

Volunteer to board?

In graduate school, I was responsible for designing and deploying a housekeeping integrate circuit (HK board). The task of this device was to control which subsystems are activated in an ARIANNA station, managing power consumption.

Figure 4: Symbolic representation of a relay bank. *Raising* the various signals S_i to a HIGH state connects the sub-system voltages V_i to power sources at the given voltages, and setting them to LOW state powers down the subsystems.

In software, the C-code interpreted a *bit-mask* in hexadecimal, which the single-board computer (SBC) would send to the digital IO (input/output), connected to the S_i lines. For example, $0b11100000$ activated only the 3V subsystems.

Figure 5: The S_i lines were controlled by the system digital IO. The above bit-mask was sent from the C-code through the digital IO.

HEXADECIMALS, BCD, GRAY-CODES, AND ASCII

However, to save space on a hard drive that only had 4 GB of space, with potentially thousands of defined functions that had to send bit masks, the manufacturer designed the base bitmasking function input as a hex word (two hex characters). In this case, it would have been $0xE0 = 0b11100000$.

Figure 6: A bitmask of D0.

Figure 7: The general case for the relay bank.

1. What hex word would activate only the 5V systems?
2. What hex word would activate only the 12V systems?
3. What hex word would activate just S_1 , S_4 , and S_7 ?

Other codings with binary and hexadecimals:

- Binary coded decimals
- Gray codes
- ASCII

Binary coded decimals (BCD):

The 8421 BCD system is often used in digital displays, readouts and number pads. It combines the familiarity of decimal digits with the utility of binary.

For example:

$0d234 = 0010\ 0011\ 0100$ in BCD.

0	0000
1	0001
2	0010
3	0011
4	0100
5	0101
6	0110
7	0111
8	1000
9	1001

Table 3: The 8421 coding for BCD. Each four-digit bit sequence represents one decimal digit.

Quick exercise: Write your first name as a decimal string (A = 1, B = 2, etc.) and convert it to BCD.

Jordan corresponds to 10 15 18 04
01 14 so 00010000 00010101
00011000 00000100 00000001
00010100

Decimal digit	BCD
0	0000
1	0001
2	0010
3	0011
4	0100
5	0101
6	0110
7	0111
8	1000
9	1001

Table 4: The 8421 coding for BCD. Each four-digit bit sequence represents one decimal digit.

The Gray Code:

The Gray code is a non-arithmetic code word system, related to binary, that minimizes transition errors by restricting one bit change per transition.

Binary to Gray Code conversion

1. The MSB is conserved.
2. Add consecutive binary bits starting with the MSB to obtain Gray Code bits.
3. Discard carries.

Binary	Gray Code
0000	0000
0001	0001
0010	0011
0011	0010
0100	0110
0101	0111
0110	0101
0111	0100
1000	1100
1001	1101
...	...

Table 5: The 4-bit Gray Code.

The Gray Code:

The Gray code is a non-arithmetic code word system, related to binary, that minimizes transition errors by restricting one bit change per transition.

Gray Code to Binary conversion

1. The MSB is conserved.
2. Add newest binary bit to next Gray Code bit to obtain next new binary bit.
3. Discard carries.

Binary	Gray Code
0000	0000
0001	0001
0010	0011
0011	0010
0100	0110
0101	0111
0110	0101
0111	0100
1000	1100
1001	1101
...	...

Table 6: The 4-bit Gray Code.

Other codings with binary and hexadecimals:

- Binary coded decimals
- Gray codes
- ASCII - American Standard Code for Information Interchange

Figure 8: An ASCII table, used in computer science for encoding text from standard input.

Example: compiling the following C++ code on some machines still *rings the bell*.

```
#include <stdio.h>
using namespace std;
int main()
{
    char y = 7;
    printf("%c\n",y);
    return 0;
}
```

Often used in systems and code involving exchanging strings of text.

CONCLUSION

Reading: Digital Fundamentals (DF) Ch. 2 (see Moodle)

1. Number representation
2. Binary conversions
3. Binary arithmetic
4. The floating-point system
5. Hexadecimals, Binary-Coded Decimals (BCD), Gray codes, and ASCII

Homework: exercises 5-16, 19-32, 35-38, 45, 53, 58 Ch. 2 (DF) (two weeks).
